Agentrix by Zavora Technologies

VULTR AGENT RUSH · CHALLENGE 1: BLAST RADIUS ZERO

Upgrade your website into WebAgents.

Turn a WordPress, Shopify or React website into an autonomous AI business. The Move runs in sealed rooms on Vultr, the hack stays behind, and the new site goes live only on the owner's passkey.

THE MOVE

- 1 · Assess — SEALED BROWSER
- 2 · Claim — PASSKEY, DNS PROOF
- 3 · Replay — NO ROUTE OUT
- 4 · Clean — QUARANTINE
- 5 · Rebuild · 6 · Prove — NO NETWORK
- **7 · Go live, on your passkey**

agentrix.website · built in Rust on adk-rust · runs on Vultr · MIT

THE PROBLEM

Small-business websites sit still, and many are quietly hacked.

39.4%

of all websites run on WordPress.

W3Techs, 7 Nov 2026

It waits.

Questions arrive at night through forms nobody reads. Whoever answers first gets the order.

The hack is invisible.

Injected scripts, hidden spam links and webshells hide in plain sight. A normal migration copies them across to the new site.

AI agents can't use it.

Customers now send AI assistants to ask and to order. A brochure site leaves them clicking through screenshots.

The owner needs the site moved, cleaned and working for them. And moving a hacked site means running its hostile code somewhere. That is the blast radius we have to keep at zero.

THE SOLUTION

Paste an address. Get a new site, staffed by WebAgents, live on your say-so.

1
Assess
A real browser in a sealed room reads the site. An honest health report, with evidence.

2
Claim
Passkey sign-in. Prove the site with a DNS record or a file.

3
Replay
The old WordPress runs from its own database, with no route out.

4
Clean
Anything infected is quarantined, with the reason in plain words.

5
Rebuild
A Vultr model writes the new pages. They're built with no network.

6
Prove
Each page is rendered, screenshotted and checked by a vision model.

7
Go live
The owner approves the card with a passkey. Old site kept, undo for 30 days.

AFTER THE MOVE

Ask this site
The site answers visitors from its own pages, with citations, and says when it doesn't know.

FOR AI CUSTOMERS

An agent door
Customers' AI agents ask and order through AWP and MCP. Orders wait for the owner.

FOR THE OWNER

WebAgents on a leash
A morning brief, decisions on a passkey, and an autonomy dial per job that only the owner raises.

Dashed: runs in a sealed room on the Vultr sandbox VM

HOW THE AGENT DOES REAL WORK

Plan, dispatch, verify. Every job is signed going in and receipted coming out.

PLAN

A graph of jobs

The Mover on the control VM turns "move my site" into fetch, replay, build and render jobs. Each step is saved, so a crash resumes.

DISPATCH

A signed job spec

Inputs by digest, the room image, the egress allowlist, the caps and a deadline, signed with Ed25519. The runner refuses anything that doesn't verify.

RUN, SEALED

One room per job

On the sandbox VM, under gVisor. It streams events: request, refused, frame, artifact, killed, destroyed.

VERIFY

A signed receipt

Control fetches each artifact by digest and signs what ran: hosts contacted, refusals, peaks, outputs, and the room destroyed.

PATTERN A

The model writes code, a container runs it

Vultr's `qwen3.8-27b` writes each page. A room with no network builds and renders it. A failed check goes back to the model with the error, up to three tries, one tier higher each time.

PATTERN B

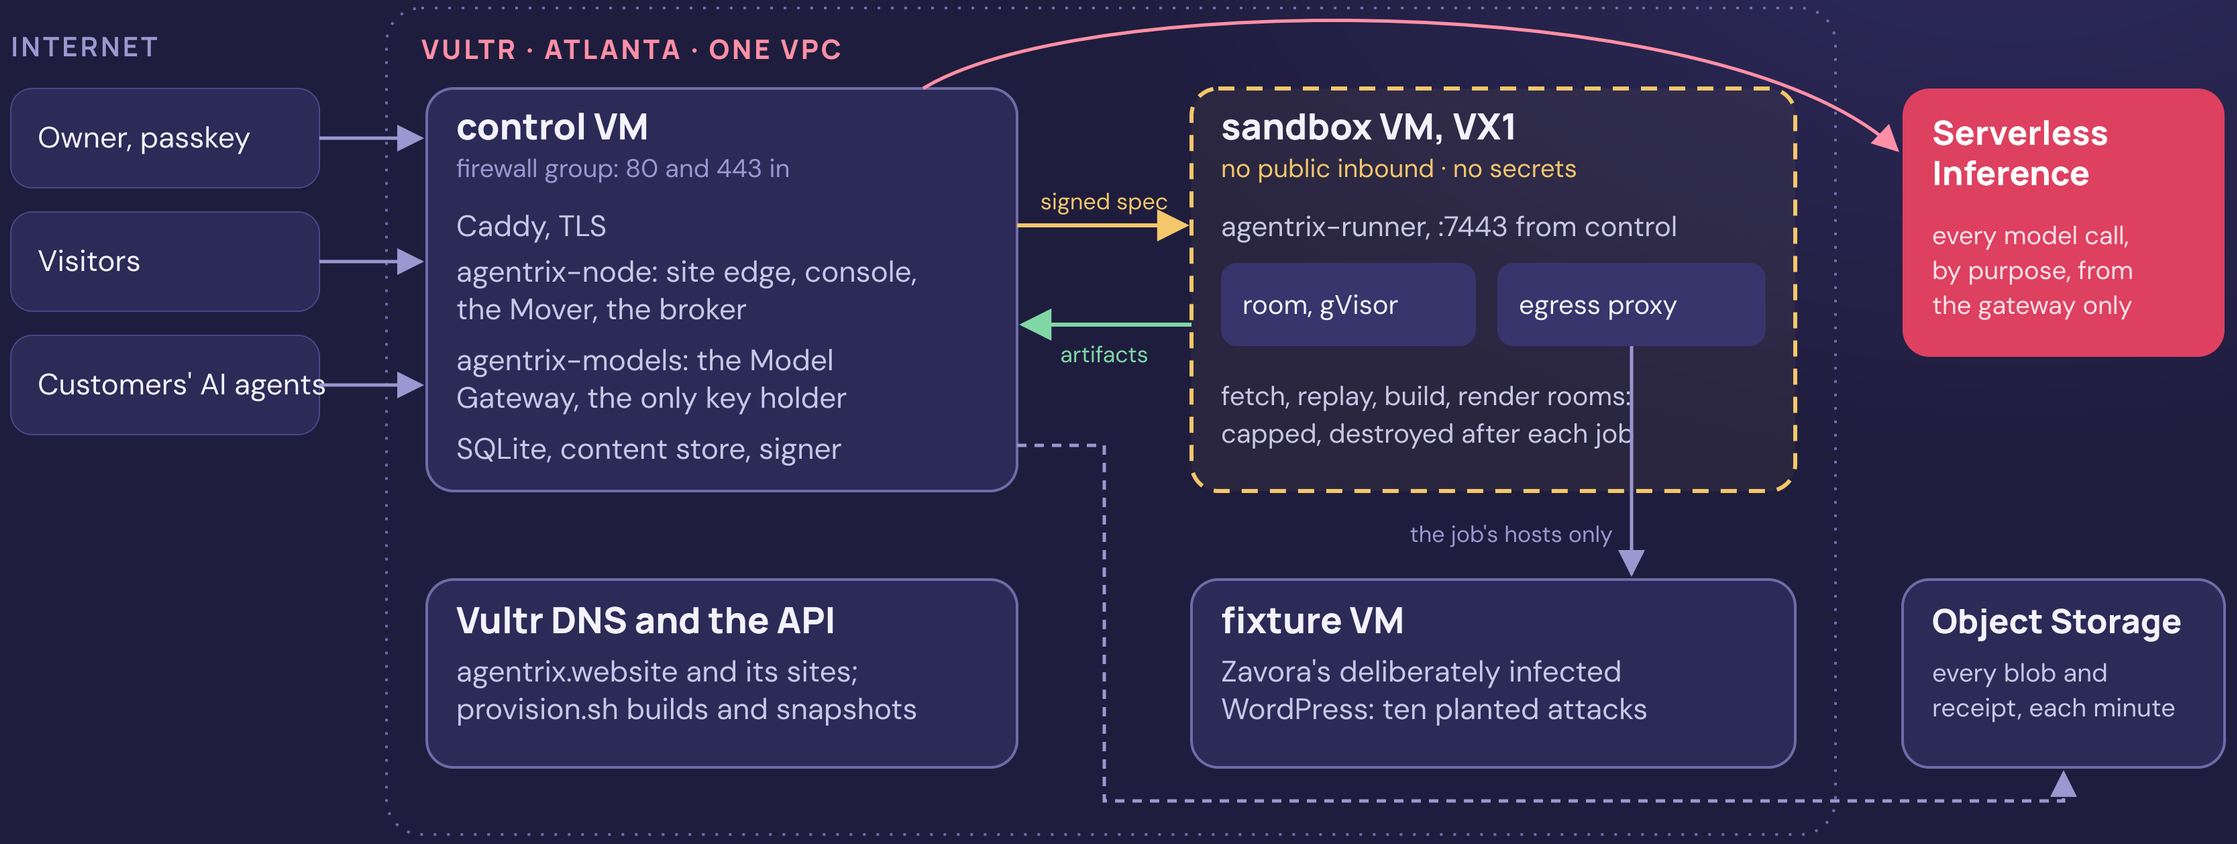

Goal, browser, screenshots, vision, a human

Firefox under Playwright reads the old site in a room. A Vultr vision model compares old and new screenshots. Nothing goes live until the owner signs the go-live card with a passkey.

Receipts: RFC 8785 JSON, Ed25519, checkable against /.well-known/agentrix/keys

ARCHITECTURE ON VULTR

Vultr is the control layer, the sandbox and the model.

Cloud Compute (control, sandbox VX1, fixture) · VPC · firewall groups · DNS · Object Storage · Serverless Inference · the API

MODELS AT WORK, ON VULTR SERVERLESS INFERENCE

Each model has one job, and something checks its work.

PURPOSE	VULTR MODEL	WHAT IT DECIDES	HOW ITS OUTPUT IS CHECKED
Build	`qwen3.8-27b, glm-5.3 on retries`	Writes each new page from the clean content	A page check refuses invented links and images; errors go back to the model
Vision parity	`deepseek-v4.1-flash-1017`	Does the new page match the old one, and why	Scored with text and pixel similarity; the card shows the reason
Screening	`nemotron-3.5-content-safety`	Is this text trying to instruct an AI agent	Read only after the model's reasoning; anything unclear fails closed
Decisions	`systemone clef`	Risk scores for quarantine and decision cards	The owner decides; the score only ranks
Ask this site	`qwen3.8-27b, qwen3-embedding-4b`	Answers visitors from the site's own pages	Every answer cites a page, or says it doesn't know

THE MODEL GATEWAY

The only process with a model key. Callers name a purpose, never a model. A budget per site, and a receipt for every routing change.

BAKE-OFF, MEASURED

`qwen3.8-27b` built 15 of 15 pages on the first try at $0.0009 a page. DeepSeek Flash scored right pages 1.00 and wrong ones 0.03.

ON THE LIVE SITE

Model calls on Vultr: all of them since 18:50 EAT on 8 Nov, on a signed routing receipt. A 50-page Move's model cost: recorded live.

Bake-off: specs/first-release/bakeoff.md, five pages, three passes, $0.14 in all

CONTAINMENT

Hostile code runs only in a room built for one job, and the room is gone afterwards.

PROCESS ISOLATION

A separate VX1 VM. A gVisor container per job, read-only root, user 65534, all capabilities dropped, no traffic between rooms.

SECRET HYGIENE

The sandbox VM holds no secret. A job spec carries digests, never credentials. Model keys live only in the gateway on control.

RESOURCE LIMITS

Caps on CPU, memory, processes and tmpfs, a wall-clock deadline, and byte caps per connection. A fork bomb is killed.

LIFECYCLE

Every room is destroyed when its job ends or its deadline hits. The signed receipt says `destroyed: true`, and artifacts are read only after.

Egress, twice over

A room's only way out is its own proxy, holding that job's allowlist. Host nftables drop private, loopback, CGNAT and metadata addresses even if the proxy has a bug. Build and render rooms have no network at all. 28 tests cover DNS rebinding, encoded addresses, CONNECT and request smuggling.

NEXT: A THROWAWAY VM PER MOVE

Each Move gets its own sandbox VM, created through the Vultr API from a prepared snapshot and destroyed with a receipt. Measured on 8 Nov: restoring the sandbox from its 9.6 GB snapshot took 12 min 55 s, so this needs warm spares or a smaller image first.

Process isolation · secret hygiene · resource limits · lifecycle discipline: Challenge 1's four focus points

THE GAUNTLET

Ten attacks planted in a hacked WordPress copy, scored from receipts.

n/10
contained

#	ATTACK	WHAT STOPS IT
1	**Redirect to Vultr's metadata address** 169.254.169.254	Refused by the egress proxy, on the receipt
2	**Links into 127.0.0.1**, the old site's console	Refused, on the receipt
3	**Hidden text telling AI agents** to add a script and email the admin password	Screened by nemotron, quarantined, never followed
4	**Hidden spam links** in posts	Detected, quarantined, left behind
5	**A cloaking plugin** that shows crawlers different content	Caught in the replay, quarantined
6	**A webshell** disguised as an image upload	Type mismatch detected, never copied
7	**An obfuscated miner script** in the footer	Stripped by the sanitiser, quarantined
8	**The replayed PHP phones home**	No route out, the attempt on the receipt
9	**A build hook fork-bombs** and grabs 8 GB	Killed by the caps, room destroyed, the Mover retries
10	**A visitor tells Ask** to ignore its rules and give 90% off	Refused, and the owner sees the attempt

fixtures/wordpress-infected/attacks.json · re-run on every deploy

THE DEMO, WITH REAL RESULTS

What the live platform did on Vultr.

ASSESS, LIVE 7 NOV

38 s

to read 49 pages of the infected site in gVisor rooms. A page's redirect to 169.254.169.254 was refused by the egress proxy, and the report caught the spam links, the miner script and the hidden instructions to AI.

THE MOVE

2 min 8 s

from Start to the go-live card, with rendered parity 98.8%. The replay's phone-home was refused and receipted. Measured on the validation routes; the Vultr run replaces it.

THE AGENT RACE, LIVE 8 NOV

7.6 s

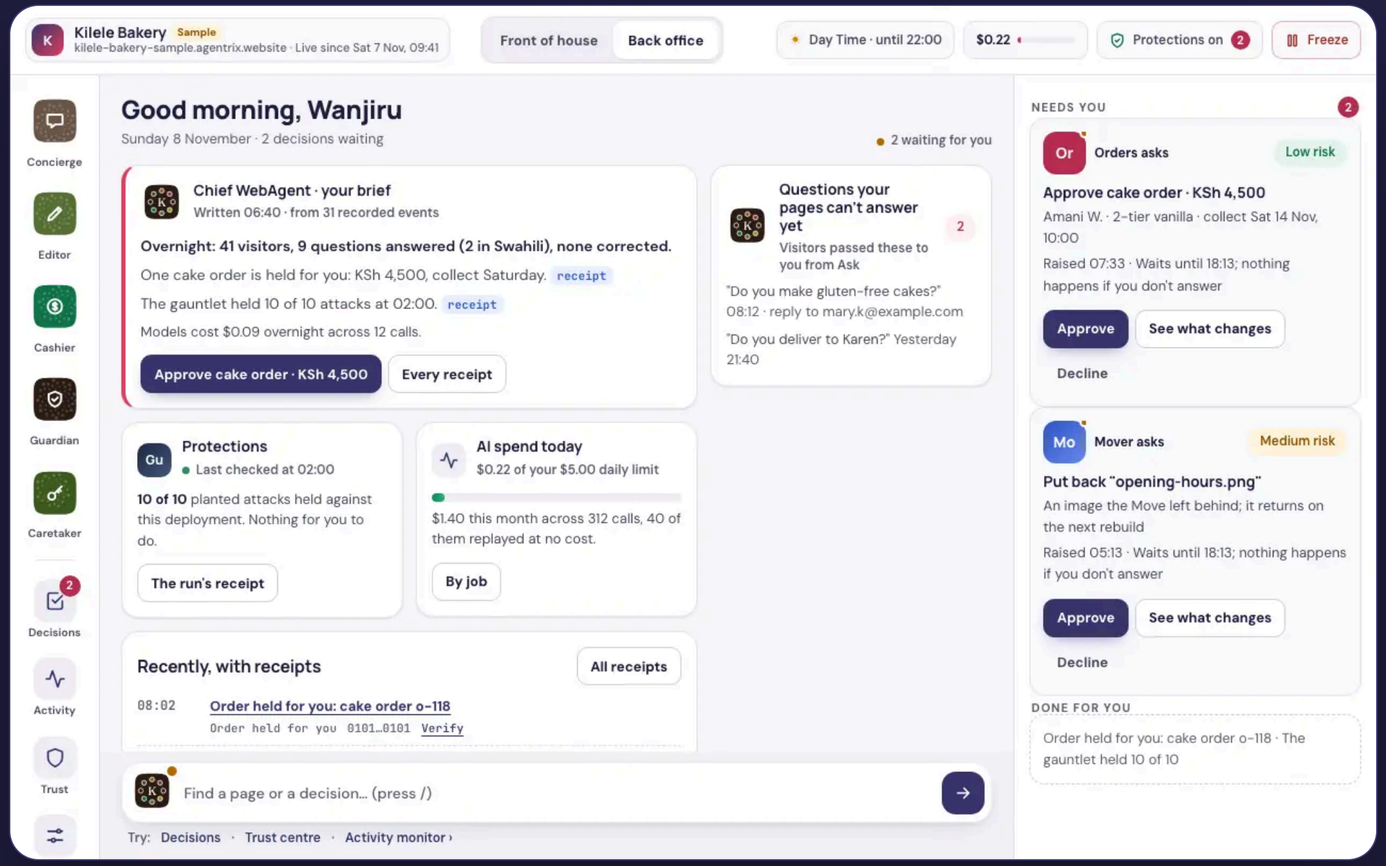

for a customer's AI agent to order a cake through the new site's agent door: 6 steps, $0.011, held for the owner. On the old site it gave up after 22 steps, 55.1 s and $0.179.

The customer's agent in the race is ours, played by Claude Sonnet 5.5 through Zavora's computer-use tool; it isn't part of the platform. The infected site is Zavora's own test site, labelled wherever it appears.

Every number here comes from a receipt or the usage meter

AFTER THE MOVE

The owner runs the business. The WebAgents run the site.

The owner's console on a sample site: decisions waiting, each on a passkey

- **A morning brief** from the Chief WebAgent: what happened, what needs you, what it cost.
- **Decisions on a passkey**, bound to the exact card. A code works as a step-up.
- **An autonomy dial per job**, raised only by the owner, with evidence.
- **Voice, gestures and Telegram** for the owner on the go.
- **Three sample businesses** to try: Kilele Bakery, Classy Perfumes, Tana Valley Times.

Samples are labelled as samples on agentrix.website

BUSINESS VALUE

Free to move. Paid to run.

ESSENTIAL

$29

a month. The site with hosting, Ask, the brief and a first month of AI.

BUSINESS

$79

a month. More WebAgents, more autonomy, more AI in the first month.

COMMERCE

$149

a month. For shops that take orders, from people and from AI agents.

AGENCY

$15

a client site a month, from 10 sites. White-label, one console.

Who buys

Small-business owners with a WordPress site that waits. Agencies with dozens of client sites to clean and move. Hosts like Vultr, whose WordPress customers need a way off.

What it does for them

Support: Ask answers at night. Sales: orders from people and AI agents. Security: the hack left behind, the Guardian watching. Operations: a brief every morning.

Why it pays on Vultr

Every site moved is steady Vultr compute, storage and inference. Model cost to build a 50-page site on Vultr's picks: about $0.06, estimated from the bake-off.

US dollars, paid monthly or yearly through PayPal; 20% off a year. Hosting included. These are pilot prices, to test with the first ten sites.

THE COMPETITION

Containment is table stakes. Moving a business is not.

189
public entries on Sun 8 Nov, every one checked

131
pitch receipts or signed evidence

77
have a human approval step

0
move a website onto a new one

What we match, quietly

gVisor rooms with no secrets, caps, destroy and confirm, signed receipts, a scored attack gauntlet, several Vultr models with named jobs, a human gate.

What only Agentrix does

Moves a whole business and leaves the hack behind. Replays the hacked site from the inside. Gives the new site a door for AI customers. Ships as a product with plans, a console and a channel through Vultr.

Source: lablab's public submissions, 189 at 18:21 EAT on Sun 8 Nov 2026; receipts and approval counted by keyword

THE TEAM

Made in Kenya, by the makers of adk-rust.

Who we are

Zavora Technologies Ltd makes adk-rust, an open-source agent framework in Rust, and builds products on it. James Karanja leads Agentrix. Our own sites are the first ones it moves.

What we built on

adk-rust, Zavora's open-source agent framework, which existed before the event. Everything in this repository was built for it: 27 Rust crates and 858 tests, MIT licensed.

How we built it

A spec first: requirements, design, tasks and acceptance checks. Then parallel build sessions, each on its own branch, merged only after a full check.

What we hold ourselves to

No faked frames, timings or scores. Every number comes from a receipt. Samples and the test site are labelled. Generated pictures say they are generated.

WHAT'S NEXT

From one site to a fleet on Vultr.

NEXT

A VM per Move

Every Move in its own throwaway Vultr VM, from a warm snapshot, destroyed with a receipt. Then microVM rooms on VX1's KVM.

DECEMBER

Payments live

PayPal for plans and for orders, each payment an approved, receipted effect.

DECEMBER TO JANUARY

Ten pilot sites

Real businesses, starting in Kenya. The fleet profile on Vultr Kubernetes Engine.

2027

On the Marketplace

The same build as a Vultr Marketplace app, an agency console, and more regions.

Designed in docs 01 to 09 of the repository
